Abstract:

The present era has witnessed tremendous growth of the internet and various applications that are running over it. Cloud computing is the internet based technology, emphasizing its utility and follows pay-as-you-go model, hence became so popular with high demanding features. Load balancing is one of the interesting and prominent research topics in cloud computing, which has gained a large attention recently. Users are demanding more services with better results. Many algorithms and approaches are proposed by various researchers throughout the world, with the aim of balancing the overall workload among given nodes, while attaining the maximum throughput and minimum time. In this paper, various proposed algorithms addressing the issue of load balancing in Cloud Computing are analyzed and compared to provide a gist of the latest approaches in this research area.

Keywords:

Cloud Computing; Green Computing; Load Balancing; Virtualization

1. INTRODUCTION

Cloud Computing is the most recent emerging paradigm promising to turn the vision of “computing utilities” into reality, it provides a flexible and easy way to store and retrieve huge data without worrying about the hardware needed. As the number of users on cloud increases, the existing resources decreases automatically which leads to the problem of delay between the users and the cloud service providers. Thus, the load balancing comes into the picture. The traffic over the network must be dealt smartly such that the situation in which some nodes are overloaded and some other are under loaded should never arise. To overcome this situation, many load balancing algorithms are proposed by researchers, with their own pros and cons.

In this paper, an overall review of the current load balancing algorithms in the Cloud Computing environment is presented. The ideas of each algorithm are discussed and finally summarized as an overview.

The rest of the paper is organized as follows. The issues related to load balancing in cloud computing environment are discussed in Section 2. In Section 3, the current literature and the load balancing algorithm in cloud proposed by various researchers were discussed. In section 4, the proposed approaches were

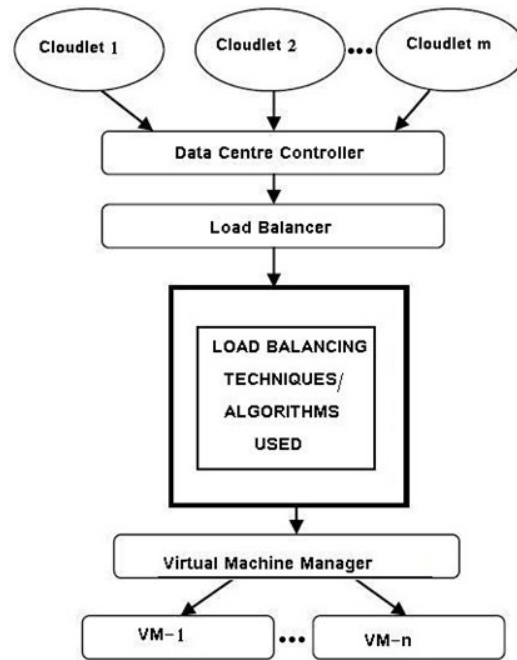

Figure 1. Load Balancing Algorithms Execution

discussed and compared. Finally, in Section 5 we concluded the paper and also presented some ideas which can be implemented in the future.

2. ISSUE EFFECTING LOAD BALANCING IN CLOUD COMPUTING

There are various issues while dealing with load balancing in a cloud computing environment. Each load balancing algorithm must be such as to achieve the desired goal. Some algorithms aims at achieving higher throughput, some aims at achieving minimum response time, some other aims to achieve maximum resource utilization while some aims at achieving a trade-off between all these metrics. **Figure 1** presents a framework under which various load balancing algorithms work in a cloud computing environment.

Some major issues which must be considered while designing any load balancing algorithm are as follows:

2.1 Geographical distribution of nodes

The geographical distribution of the nodes matters a lot in the overall performance of any real time cloud computing systems, especially in case of the large scaled applications like Facebook, Twitter, etc. A well-distributed system of nodes in cloud environment is helpful in handling fault tolerance and maintaining the efficiency of the system.

2.2 Dynamic Vs Static behavior of algorithms

Any algorithm concerning load balancing is designed, based on the state or behavior of the system, which may be static or dynamic.

2.2.1 Static Algorithms

These algorithms do not depend upon the current state of the system and have prior knowledge regarding system resources and details of all tasks in an application. These kinds of algorithms face a major drawback in case of sudden failure of system resource and tasks.

2.2.2 Dynamic Algorithms

These algorithms take decisions concerning load balancing based upon the current state of the system and don't need any prior knowledge about the system. This approach is an improvement over the static approach. The algorithms in this category are considered complex, but have better fault tolerance and overall performance.

2.3 Algorithm Complexity

The complexity of any load balancing algorithm affects the overall performance of the system. Sometimes the algorithm is complex, but is better in terms of throughput and resource utilization. On the other hand, the algorithms which are simpler in terms of complexity may give poor performance in terms of fault tolerance, migration time and response time. Therefore, based on the system requirements, care should be taken to decide a better or suitable load balancing algorithm. A trade-off between all the parameters must be set wisely.

2.4 Traffic analyses over different geographical location.

For any load balancing algorithm, it is very important to analyze the traffic flow in real-time scenarios over different geographic regions, and then balance the overall workload accordingly. All regions over the globe have a different time zone and have certain peak hours during which the network load is supposed to be at its peak. Therefore, load balancer must be capable of handling the traffic in peak hours in every location so as to achieve maximum resource utilization and throughput.

3. EXISTING LOAD BALANCING TECHNIQUES IN CLOUD COMPUTING

In this section, some significant contributions on load balancing in cloud computing, as mentioned in the literature are discussed. A. Khiyaita *et al.* [1], in their paper gave an overview of load balancing in

cloud computing, classification of load balancing algorithms based upon system load and system topology, examples of load balancing and different research challenges in load balancing. While in [2] authors discussed most of the existing techniques which are aimed at reducing the associated overhead, service response time and improving performance of the technique. The paper also provides details about various parameters, used to compare the existing techniques. D. A. Menasce *et al.* [3] discussed the concept of cloud computing, its advantages, disadvantages and described several existing cloud computing platforms. He also discussed the results of quantitative experiments carried out using PlanetLab, a cloud computing platform and capacity planning methods for cloud users and cloud service providers. To maintain the load balancing in the cloud computing system, Kuo-Qin Yan *et al.* [4] proposed a scheduling algorithm. Their algorithm combined the capabilities of both OLB (Opportunistic Load Balancing) [5] and LBMM (Load Balance Min-Min) [6] scheduling algorithms, and is comparatively more efficient. In [7], idea is to find the best cloud resource while considering Co-operative Power aware Scheduled Load Balancing, solution to the Cloud load balancing challenge. The algorithm proposed in this paper, utilizes the benefits of both distributed and centralized approach of computing. Inherent efficiency of centralized approach as well as the energy efficiency and fault-tolerance nature of distributed approach is well used in this algorithm.

In PALB [8] approach, the utilization percentages of each compute node is estimated. This helps in deciding the number of compute nodes which must keep operating while other nodes completely shuts down. The algorithm has three sections: Balancing section, Upscale section and Downscale section. Balancing section is responsible for determining where virtual machines will be instantiated based on utilization percentages. The upscale section power-on's the additional compute nodes. And the downscale section shut-downs the idle compute nodes. This algorithm is guaranteed to decrease the overall power consumption while maintaining the availability of resources as compared to other load balancing algorithms. Raul Alonso-Calvo *et al.* [9] have discussed on managing large image collections in companies and institutions. A cloud computing service and its application for storage and analysis of very large images have been created and the data operations are adapted for working in a distributed mode by using different sub-images that can be stored and processed separately by different agents in the system, facilitating processing very-large images in a parallel manner. This work can be viewed as another way of load balancing in cloud computing. Apart from availability of resources, other factors like scaling of resources and power consumption are also important concerns in load balancing that cannot be ignored. Load balancing techniques should be such as to obtain measurable improvements in resource utilization and availability of resources in the cloud computing environment [10]. Alexandru Iosup *et al.* [11] Analyzed the performance of cloud computing services for scientific computing workloads and quantified the presence in real scientific computing workloads of Many-Task Computing (MTC) users, that is, of users who employ loosely coupled applications comprises many tasks to achieve their scientific goals. They also perform an empirical evaluation of the performance of four commercial cloud computing services.

Srinivas Sethi *et al.* [12] proposed a load balancing algorithm using fuzzy logic in a cloud computing environment. This algorithm uses two parameters processor speed and assigned a load of virtual machine, to balance the overall load through fuzzy logic, although in [13], the authors have introduced a new fuzzy logic based dynamic load balancing algorithm with additional parameters- memory usage, bandwidth usage, disk space usage and virtual machine status and named it as Fuzzy Active Monitoring Load Balancer (FAMLB). Milan E. Sokile [14], have discussed different load balancing techniques in a distributed environment, namely diffusive load, static, round robin and shortest queue in different client environments. Experimental analysis have been done showing diffusive load balancing is more efficient than static and round robin load balancing in a dynamic environment. Ankush P. Deshmukh and Prof. Kumaraswamy Pamu [15], discussed on different load balancing strategies, algorithms and methods. The

research also shows that the dynamic load balancing is more efficient than other static load balancing techniques. Efficient load balancing can clearly give major performance benefits [16]. A Network Processor consists of a number of on-chip processors to carry out packet level parallel processing operations, ensuring good load balancing among the processors. This process increases the throughput of the system. However, such type of multiprocessing increases out-of-order departure of processed packets. In this paper, the authors first propose an Ordered Round Robin (ORR) scheme to schedule packets in a heterogeneous network processor, assuming that the workload is perfectly divisible. The processed loads from the processors are perfectly ordered. This paper analyzes the throughput and derives expressions for the batch size, scheduling time and maximum number of schedulable processors. Jaspreet Kaur [17] has discussed active vm load balancer algorithm to find a suitable virtual machine in less time period. She has done simulation showing comparative analysis of round robin and equal spread current execution policies of load balancing with varying service broker policies for data center in a cloud computing environment and compared their response time and cost.

Zhang Bo *et al.* [18], proposed an algorithm which adds capacity to the dynamic balance mechanism for the cloud. The experiments demonstrate that the algorithm has obtained a better load balancing degree and used less time in loading all tasks. Soumya Ray and Ajanta De Sarkar [19] have discussed various algorithms of load balancing like Round robin algorithm, Central queuing algorithm and Randomized algorithm, their analysis is carried out on MIPS vs. VM and MIPS vs. HOST basis. Their results demonstrate that these algorithms can possibly improve the response time in order of magnitude, with respect to number of VMs in Datacenter. Execution analysis of the simulation shows that the change of MIPS will affect the response time. Increasing MIPS vs. VM decreases the response time. In order to handle the random selection based load distribution problem, dynamic load balancing algorithm can be implemented as the future course of work to evaluate various parameters. In [20], the authors have proposed an algorithm on load distribution of workloads among nodes of a cloud, by the use of Ant Colony Optimization (ACO). This algorithm uses the concept of the ant colony optimization method.

Shridhar G. Domanal and G. Ram Mohana Reddy [21] have proposed a local optimized load balancing approach for distributing incoming job request uniformly between the servers or virtual machines. They analyzed the performance of their algorithm using the Cloud Analyst simulator. Further, they also compared their approach with Round Robin [22] and Throttled algorithm [23]. A similar work was done by Shridhar G. Domanal and G. Ram Mohana [21] using CloudSim and Virtual Cloud simulators. In [24], the authors have analyzed various policies in combination with different load balancing algorithms using a tool called Cloud Analyst. They presented various variants of Round Robin load balancing algorithm, demonstrating the pros and cons of each. The Dynamic Round Robin algorithm is an improvement over static Round Robin algorithm [25], this paper analyzed the Dynamic Round Robin algorithm with varying parameters of host bandwidth, cloudlet length, VM image size and VM bandwidth. Results have been analyzed based upon the simulation carried in CloudSim simulator. In [26], the authors Ching-Chi Lin, Pangfeng Liu, Jan-Jan Wu, have proposed a new Dynamic Round Robin (DRR) algorithm for energy-aware virtual machine scheduling and consolidation. This algorithm is compared with other existing algorithms, namely Greedy, Round Robin and Powersave strategies used in Eucalyptus.

4. DISCUSSION AND COMPARISON

In the previous section different load balancing techniques proposed by various researchers have been discussed. **Table 1** gives a comparative analysis of different load balancing techniques with respect to

Table 1. Comparison of existing Load Balancing Techniques

Metrics/ Techniques	Throughput	Overhead	Fault tolerance	Migration time	Response time	Resource Utilization	Scalability	Performance
Round Robin [22]	YES	YES	NO	NO	YES	YES	YES	YES
Dynamic Round Robin [26]	YES	YES	YES	YES	NO	YES	NO	NO
PALB [8]	YES	YES	YES	YES	YES	YES	NO	NO
Active Monitoring [23]	YES	YES	NO	YES	YES	YES	YES	NO
FAMLB [13]	YES	YES	YES	YES	NO	YES	YES	YES
Min-Min [6]	YES	YES	NO	NO	YES	YES	NO	YES
Max-Min [27]	YES	YES	NO	NO	YES	YES	NO	YES
OLB+LBMM [4]	NO	NO	NO	NO	NO	YES	NO	YES
Throttled [23]	NO	NO	YES	YES	YES	YES	YES	YES
Honeybee Foraging [28]	NO	NO	NO	NO	NO	YES	NO	NO
Active Clustering [28]	NO	YES	NO	YES	NO	YES	NO	NO
Biased Random Sampling [28]	NO	YES	NO	NO	NO	YES	NO	YES

different performance parameters.

In **Table 1** various metrics have been considered to compare different techniques. The metrics on which the existing load balancing techniques have been measured are discussed below:

1. *Throughput*

This metric is used to estimate the total number of tasks, whose execution has been completed successfully. High throughput is necessary for overall system performance.

2. *Overhead*

Overhead associated with any load balancing algorithm indicates the extra cost involved in implementing the algorithm. It should be as low as possible.

3. *Fault Tolerance*

It measures the capability of an algorithm to perform uniform load balancing in case of any failure. A good load balancing algorithm must be highly fault tolerable.

4. *Migration Time*

It is defined as, the total time required in migrating the jobs or resources from one node to another. It should be minimized.

5. *Response Time*

It can be measured as, the time interval between sending a request and receiving its response. It should be minimized to boost the overall performance.

6. *Resource Utilization*

It is used to ensure the proper utilization of all those resources, which comprised the whole system. This factor must be optimized to have an efficient load balancing algorithm.

7. *Scalability*

It is the ability of an algorithm to perform uniform load balancing in a system with the increase in the number of nodes, according to the requirements. Algorithm with higher scalability is preferred.

8. Performance

It is used to check, how efficient the system is. This has to be improved at a reasonable cost, e.g., reducing the response time though keeping the acceptable delays.

5. CONCLUSION AND FUTURE WORK

In this paper, we have surveyed various load balancing algorithms in the Cloud Computing environment. We discussed major issues which must be taken into consideration while designing any load balancing algorithm. We have discussed the already proposed algorithms by various researchers in literature, their advantages and disadvantages. A comparison has been done on the basis of different criteria like scalability, network overhead, resource utilization, algorithm complexity, fault tolerance, response time, etc. In future we will focus on designing algorithms which will maintain a better trade-off among all performance parameters.

About This Journal

MCCC is an open access journal published by Scientific Online Publishing. This journal focus on the following scopes (but not limited to):

- Autonomic Business Process and Workflow Management in Clouds
- Cloud Composition, Federation, Bridging and Bursting
- Cloud Computing Consulting
- Cloud Configuration, Performance and Capacity Management
- Cloud DevOps
- Cloud Game Design
- Cloud Migration
- Cloud Programming Models and Paradigms
- Cloud Provisioning Orchestration
- Cloud Quality Management and Service Level Agreement (SLA)
- Cloud Resource Virtualization and Composition
- Cloud Software Patch and License Management
- Cloud Workload Profiling and Deployment Control
- Cloud Video and Audio Applications
- Economic, Business and ROI Models for Cloud Computing
- Green Cloud Computing
- High Performance Cloud Computing
- Infrastructure, Platform, Application, Business, Social and Mobile Clouds
- Innovative Cloud Applications and Experiences
- Security, Privacy and Compliance Management for Public, Private and Hybrid Clouds
- Self-service Cloud Portal, Dashboard and Analytics
- Storage, Data and Analytics Clouds
